ADHD medication in offspring of immigrants: Does the income level of the country of origin matter?

Child psychiatric treatment facilities vary greatly worldwide and are virtually non-existent in many low-income countries. Clinical studies have shown that children from immigrant families living in Sweden received less psychiatric care than those of native-born parents. However, previous studies have shown a similar prevalence of ADHD in minority and majority children in Sweden and the UK. We tested the hypothesis that the consumption of child psychiatric care in immigrant families would be determined by the availability of such treatment in the parents’ country of origin. Patterns of medication for attention-deficit hyperactivity disorder (ADHD) were studied as a proxy for child psychiatric care.

This was a register study of dispensed stimulant medication during 2013-2014 in Swedish national birth cohorts from 1995-2009, 1.4 million. The children were divided by national income of the parental country of origin and whether the parents were native Swedes, European immigrants, non-European immigrants or a mixture. Logistic regression was used to calculate the odds ratios of having been dispensed at least one ADHD drug during 2013, with adjustments for gender, family status, household income and area of residence.

Having parents born in low-income (OR [95% confidence interval] 0.27 [0.24-0.29]) or middle-income (European: OR 0.23 [0.20-0.26], non-European: OR 0.39 [0.34-0.41]) countries was associated with lower ADHD treatment levels than having parents born in high-income countries (European: OR 0.60 [0.54-0.66], non-European: OR 0.68 [0.59-0.79]), when compared to children of parents born in Sweden. In families with an origin in low or middle income countries, there was no significant association between household income and ADHD medication, while in children with Swedish and mixed backgrounds high level of disposable income was associated with lower levels of ADHD medication.
